

I Question 1

Statement 1

Why is the denominator $M - 1$ instead of M ?

$$\sigma_M^2 := \frac{1}{M-1} \sum_{i=1}^M (\xi_i - \mu_M)^2$$

简单说是因为共线性， n 个样本的自由度为 n ，但是样本都减去样本均值后自由度就变为 $n - 1$ ，所以分母上应为 $n - 1$ 。证明思路为

$$\begin{aligned} E \left[\frac{1}{n} \sum_{i=1}^n (X_i - \bar{X})^2 \right] &= E \left[\frac{1}{n} \sum_{i=1}^n ((X_i - \mu) - (\bar{X} - \mu))^2 \right] \\ &= E \left[\frac{1}{n} \sum_{i=1}^n (X_i - \mu)^2 \right] - E \left[\frac{1}{n} \sum_{i=1}^n (\bar{X} - \mu)^2 \right] \\ &= \sigma^2 - \frac{1}{n} \sigma^2 = \frac{n-1}{n} \sigma^2 \end{aligned}$$

因此我们得到满足 $E[S^2] = \sigma^2$ 的无偏估计

$$S^2 = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2.$$

2 Question 2 and 3

Statement 2

Try both cases in computer simulations and what is your observation? Prove that the $M - 1$ case is better in the statistical sense.

运行程序如下，其中共进行 65536 次实验，每次生成服从正态分布 $N(0, 1)$ 的 1024 组数据进行运算。无偏估计较好的实验次数为 33347，超过实验总数的一半以上。且多次运行程序结果相差不大，无一例外地无偏估计所得结果较好，所以使用 $M - 1$ 作为分母在统计学上是更好的选择。
